

Release Intelligence Dashboard

Mock RFP Response — github.com/him-agni/release-intelligence-dashboard

Written as a practice exercise: technical answers a Solutions Engineer would give during a buyer evaluation, based on the architecture actually implemented in this project.

Q: How does your platform help our team know if a deployment is safe within minutes of shipping it?

A: It aggregates GitHub Actions, Sentry, PostHog, and GCP Logging in parallel immediately after a deploy and turns them into a single health score and recommendation. Instead of checking four dashboards, your team gets one healthy/watch/incident signal within moments of the release finishing.

Q: What happens if one of the monitoring tools we use, like Sentry, has an outage or a slow response?

A: Each integration is queried independently using a graceful-degradation pattern. If one service fails or times out, that shows as a blank signal for that one dimension only — it doesn't block the health score from the other three sources or crash the snapshot.

Q: How do you avoid duplicate or inconsistent snapshots if a deployment webhook fires more than once?

A: Deployment snapshots are deduplicated by the CI/CD workflow run ID, so a repeated webhook delivery updates the existing snapshot rather than creating a conflicting duplicate entry.

Q: Can we see this in action before connecting our real GitHub, Sentry, PostHog, and GCP credentials?

A: Yes — a mock data mode runs the full dashboard, health scoring, and recommendation engine end-to-end with no external credentials required, so your team can evaluate the product experience before any integration work begins.

Q: What does a 'zero' reading in one of the panels mean — no data, or an error?

A: The system distinguishes explicitly between 'no data' and 'not queried.' A zero means the service was queried successfully and found no matching activity in the post-deploy window — it does not mean the integration failed silently, which matters when a team is trusting the score to make a rollback call.

Q: Can we walk through the architecture with our own engineering team before committing?

A: Yes. The flow is straightforward: a GitHub Actions deployment completes, fires a signed webhook, the API verifies the signature and fetches GitHub, Sentry, PostHog, and GCP data in parallel, computes a health score, and persists a snapshot that the dashboard displays.
