

Release Intelligence Dashboard

Solution Brief — github.com/him-agni/release-intelligence-dashboard

Problem: After every deployment, engineering teams check GitHub Actions, Sentry, product analytics, and cloud logs in separate tabs to figure out whether the release is actually safe — a slow, manual, and easy-to-skip process.

Solution: A dashboard that pulls all four signals in parallel right after a deploy and condenses them into one health score and recommendation, so the team gets a single, decision-ready answer instead of four browser tabs.

How It Works: GitHub Actions deployment completes -> signed webhook -> Express API verifies signature -> parallel fetch from GitHub Actions, Sentry, PostHog, and GCP Logging -> health score + recommendation computed -> MongoDB snapshot -> React dashboard.

Key Capabilities

- Parallel aggregation across four monitoring and analytics tools
- Graceful degradation — one vendor outage never blocks the full snapshot
- Configurable health scoring model with a clear recommendation
- Deduplication by CI/CD workflow run ID for reliable, repeatable snapshots
- Mock data mode for full evaluation with zero external credentials
- Explicit zero-vs-error distinction so a quiet signal is never mistaken for a broken integration

Business Outcome: Faster, more confident rollback decisions, less tab-switching for engineers after every release, and one accountable score instead of a subjective gut check on release health.

Tech Stack: React, Vite, Node.js, Express, MongoDB, GitHub Actions API, Sentry API, PostHog HogQL, GCP Cloud Logging API.
