

Release Intelligence Dashboard

MEDDIC Breakdown — github.com/him-agni/release-intelligence-dashboard

Self-directed practice: treating this project as a product under evaluation by a realistic buyer, to build fluency in sales qualification language used in Solutions Engineering.

M Metrics	Reduce time-to-detect a bad deploy; reduce the number of tools an engineer checks post-release; reduce incidents that were caught late because signals were spread across separate tools.
E Economic Buyer	VP of Engineering or Director of Platform Engineering — owns the budget for tooling that reduces incident response time and engineering toil.
D Decision Criteria	Accuracy and trustworthiness of the health score, graceful degradation if one vendor API is down, and ease of connecting existing tools without months of integration work.
D Decision Process	Platform team runs a pilot on one service, validates the scoring model against a real past incident, then rolls out to additional teams.
I Identify Pain	Releases regularly ship and something breaks quietly; engineers do the 'check four tabs' routine after every deploy; there's no single source of truth for whether a release was actually okay.
C Champion	The platform or DevOps lead who's tired of manually correlating GitHub Actions, Sentry, PostHog, and logs after every release.
